Visualize the Future in AAA Therapy

Nellix® is a whole new way of treating AAA, involving bi-lateral stents and a biostable and biocompatible polymer injected into conformable EndoBags that seal the entire aneurysm. That’s why it’s important to recognize some of its unique imaging features to best recognize the effectiveness of treatment and monitor disease progression.

**Nellix® Implant Imaged With CT or Ultrasound**

The Nellix® EndoVascular Aneurysm Sealing (EVAS) System is the first and only system that seals the entire aneurysmal sac – a totally different approach than conventional EVAR. However, like EVAR, follow-up imaging for Nellix® is also done by CT or ultrasound imaging.

**Visualization on Follow-up Helps Achieve Effective Treatment**

Nellix® implant features are readily visible over time, as in this CT scan, to track any disease progression and help ensure effective, long-term treatment.
Changes in Nellix® Imaging Characteristics Over Time

Images of the Nellix® EndoBags and polymer have unique characteristics, that change over time, from pre-op through follow-up.

CT Images of Nellix® Implant on Follow-Up

- **Pre Implant**
- **1 Month**
- **6 Month**

Within the first 30 days, the contrast in the polymer within the EndoBags is visible; this is not an endoleak.

After 30 days, the contrast dissipates to the edges of the polymer, making the EndoBags more visible; this is not calcium.

Being Familiar With Nellix® Characteristics Enhances Your Effectiveness

Successfully interpreting Nellix® imaging plays a key role in monitoring treatment and predicting outcomes in AAA.

Air in the EndoBag

- **1 Month**
- **6 Months**

Most air disappears at one month and diffuses across the EndoBag.

EndoBag remains unchanged in position.

Contrast vs non contrast CT

- **Contrast**
- **Non contrast**

Is recommended to surveil sac change, endoleak, patency and other morphological changes.

Radiodensity may be Uniform or Asymmetric

- Uniform radiodensity
- Asymmetric radiodensity
